Nonlinearity

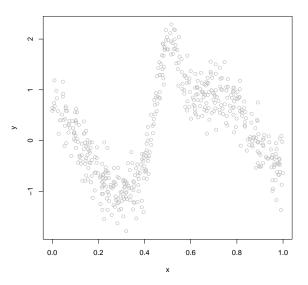

- In many situations, the relationship between x and y is not linear
- Suppose $y = f(x) + \varepsilon$ with

$$f(x) = \sin(2(4x-2)) + 2e^{-(16^2)(x-.5)^2}$$

 Even with a polynomial of degree 15, the fit is fairly poor in many areas, and 'wiggles' in some places where there doesn't appear to be a need to

Polynomial regression of degree 15

Hat matrix $X(X^tX)^{-1}X^t$ for polynomial regression of degree 15

Piecewise polynomial

- Divide the data into chunks at various points (*knots*), and fit a
 polynomial model within that subset of data
- Specify *K* internal knots on the range of *x*:

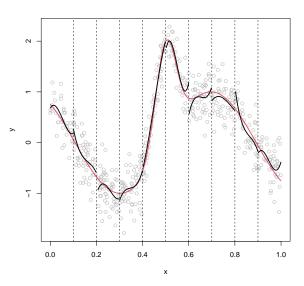

$$\min(x) < \xi_1 < \ldots < \xi_K < \max(x)$$

which define K + 1 intervals

– Fit a polynomial model of degree M on each of the K+1 intervals

$$(-\infty, \xi_1], (\xi_1, \xi_2], \dots, (\xi_{K-1}, \xi_K], (\xi_K, +\infty)$$

 A shortcoming is that at each knot the predicted values will generally not be continuous

Piecewise cubic regression

Basis expansion

$$f(x) = \sum_{j=1}^{p} \beta_j B_j(x)$$

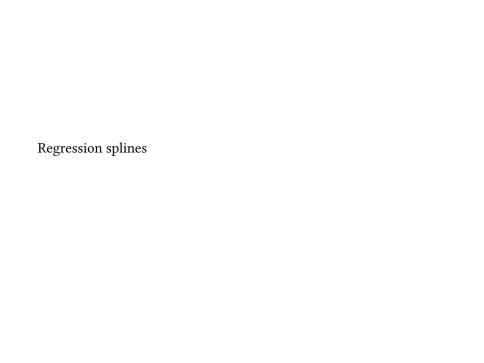

where $B_j(\cdot)$ are known functions called *basis functions*. For example

- 3rd degree polynomial:

$$B_1(x) = 1, B_2(x) = x, B_3(x) = x^2, B_4(x) = x^3$$

– Step function with *K* knots:

$$B_1(X) = \mathbb{1}\{x < \xi_1\}, B_2(x) = \mathbb{1}\{\xi_1 \le x < \xi_2\}, \dots, B_K(x) = \mathbb{1}\{\xi_{K-1} \le x < \xi_K\}, B_{K+1}(x) = \mathbb{1}\{x \ge \xi_K\}$$

Regression splines

A *spline* of degree *M* with knots ξ_1, \ldots, ξ_K

- is a polynomial of degree *M* on each of the intervals

$$(-\infty, \xi_1], [\xi_1, \xi_2], [\xi_2, \xi_3], \dots, [\xi_{K-1}, \xi_K], [\xi_K, \infty)$$

– it has continuous derivatives of orders $0, \dots, M-1$ at each knot

$$f(\xi_k^-) = f(\xi_k^+), \quad \dots, \quad f^{(M-1)}(\xi_k^-) = f^{(M-1)}(\xi_k^+), \quad k = 1, \dots, K$$

where ξ_k^+ and ξ_k^- indicate indicate the left and right limits of the function at ξ_k

Truncated power basis

- A spline of degree M with knots ξ_1, \ldots, ξ_K can be defined by the *truncated power basis*

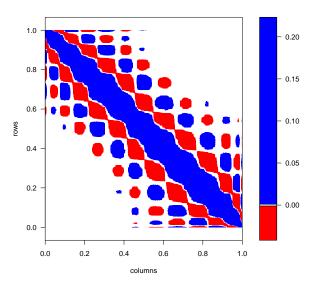

$$B_1(x) = 1$$

 $B_{j+1}(x) = x^j, \quad j = 1, ..., M$
 $B_{M+k+1}(x) = (x - \xi_k)_+^M, \quad k = 1, ..., K$

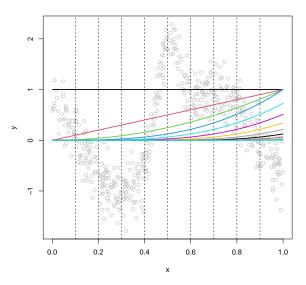

where $(\cdot)_+$ defines the positive portion of its argument, i.e.

$$(x - \xi_k)_+^M = \begin{cases} (x - \xi_k)^M & x \ge \xi_k \\ 0 & \text{otherwise} \end{cases}$$

- There are K+1 polynomials of order M and K sets of M constraints; the truncated power basis has (K+1)(M+1)-KM, or 1+M+K free parameters.

Smoothing matrix $B(B^tB)^{-1}B^t$ for polynomial regression of degree 15

Truncated power basis $B_j(x)$

- We compute the solution by explicitly constructing a $n \times (1 + M + K)$ design matrix B with

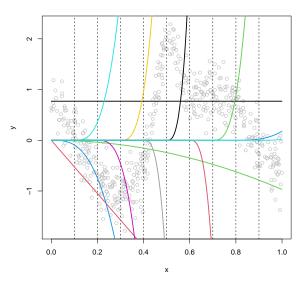

$$B_{i,j} = B_i(x_i)$$
 $i = 1, ..., n, j = 1, ..., 1 + M + K$

- The regression spline can be written as

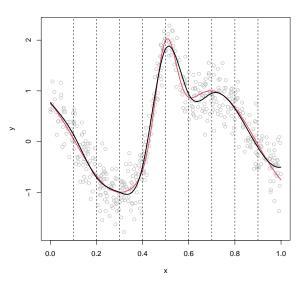

$$\hat{f}(x) = \sum_{j=1}^{1+M+K} \hat{\beta}_j B_j(x)$$

where $\hat{\beta}$ is given by

$$\hat{\beta} = (B^t B)^{-1} B^t \gamma$$

Scaled truncated power basis $\hat{\beta}_j B_j(x)$

Regression cubic spline

Natural cubic splines

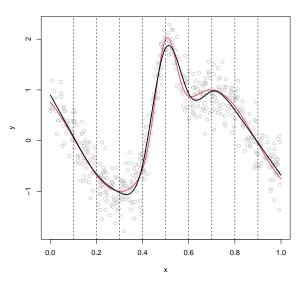

- The most commonly used are cubic splines. Splines exhibit erratic behaviour for values less than ξ_1 and larger than ξ_K
- A natural cubic spline adds additional constraints, namely that the function is linear beyond the boundary knots.
- This frees up 4 degrees of freedom: a natural cubic spline with K knots is represented by K basis functions:

$$B_{1}(x) = 1$$

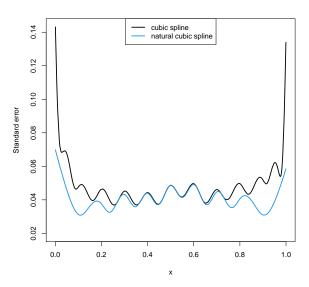

$$B_{2}(x) = x$$

$$B_{j+2}(x) = \frac{(x - \xi_{j})_{+}^{3} - (x - \xi_{K})_{+}^{3}}{\xi_{K} - \xi_{j}} - \frac{(x - \xi_{K-1})_{+}^{3} - (x - \xi_{K})_{+}^{3}}{\xi_{K} - \xi_{K-1}}$$

$$j = 1, \dots, K-2$$

Natural cubic spline

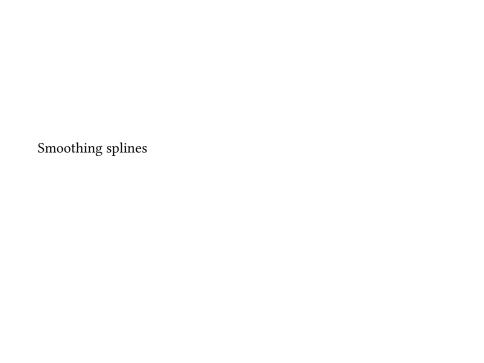

Standard error of the fit

- A set of n points (x_i, y_i) can be exactly interpolated using a natural cubic spline with the $x_1 < ... < x_n$ as knots. The interpolating natural cubic spline is unique.
- Amongst all functions on [a, b] which are twice continuously differentiable and which interpolate the set of points (x_i, y_i) , a natural cubic spline with knots at the x_i yields the smallest roughness penalty

$$\int_{a}^{b} (f''(x))^2 dx$$

- f''(x) is the second derivative of f with respect to x - it would be zero if f were linear, so this measures the curvature of f at x.

Smoothing spline

- Smoothing splines circumvent the problem of knot selection by performing regularized regression over the natural spline basis, placing knots at all inputs x_1, \ldots, x_n
- With inputs $x_1 < \ldots < x_n$ contained in an interval [a, b], the minimiser of

$$\hat{f} = \arg\min_{f \in C_2} \sum_{i=1}^n (y_i - f(x_i))^2 + \lambda \int_a^b (f''(x))^2 dx$$

amongst all twice continuously differentiable functions on [a, b] is given by a a natural cubic spline with knots in the unique x_i

- The previous result tells us that we can choose natural cubic spline basis B_1, \ldots, B_n with knots $\xi_1 = x_1, \ldots, \xi_n = x_n$ and solve

$$\hat{\beta}_{\lambda} = \arg\min_{\beta} \sum_{i=1}^{n} (y_i - \sum_{i=1}^{n} \beta_j B_j(x_i))^2 + \lambda \int_a^b \left(\sum_{i=1}^{n} \beta_j B_j''(x)\right)^2 dx$$

to obtain the smoothing spline estimate $\hat{f}(x) = \sum_{i=1}^{n} \hat{\beta}_{j} B_{j}(x)$

- Rewriting

$$\hat{\beta}_{\lambda} = \arg\min_{\beta} \|y - B\beta\|^2 + \lambda \beta^t \Omega \beta$$

where $B_{ij} = B_j(x_i)$ and $\Omega_{jk} = \int B_j''(x)B_k''(x)dx$, shows the smoothing spline problem to be a type of generalized ridge regression problem with solution

$$\hat{\beta}_{\lambda} = (B^t B + \lambda \Omega)^{-1} B^t y$$

- Fitted values in Reinsch form

$$\hat{y} = B(B^t B + \lambda \Omega)^{-1} B^t y$$
$$= (I_n + \lambda K)^{-1} y$$

where $K = (B^t)^{-1}\Omega B^{-1}$ does not depend on λ , and $S = (I_n + \lambda K)^{-1}$ is the $n \times n$ smoothing matrix

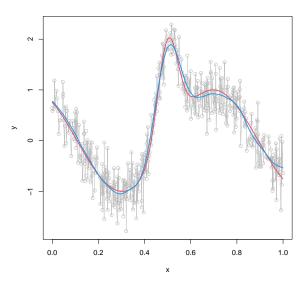

Leave-one-out cross validation

$$LOO = \frac{1}{n} \sum_{i=1}^{n} \left(\frac{y_i - \hat{y}_i}{1 - S_{ii}} \right)^2$$

- Generalized cross validation

$$GCV = \frac{1}{n} \sum_{i=1}^{n} \left(\frac{y_i - \hat{y}_i}{1 - \text{tr}(S)/n} \right)^2$$

where tr(S) is the effective degrees of freedom

smooth.spline result with $\lambda=0$ and 6.9e-15 by LOO

Reinsch original solution

The original Reinsch (1967) algorithm solves the constrained optimization problem

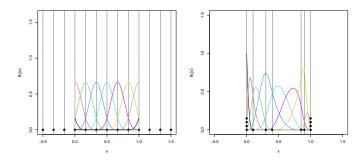

$$\hat{f} = \arg\min_{f \in \mathcal{C}_2} \int_a^b (f''(x))^2 dx$$
 such that $\sum_{i=1}^n (y_i - f(x_i))^2 \le c$

- The previous formulation with a Lagrange parameter on the integral smoothing term instead of the least squares term is equivalent
- See casl_smspline implementation in Section 2.6 of CASL

B-spline basis

- The truncated power basis suffers from computational issues.
 The *B*-spline basis is a re-parametrization of the truncated power basis spanning an equivalent space
- The appearance of *B*-splines depends on their knot spacing, e.g.
 - uniform B-splines on equidistant knots;
 - non-uniform *B*-splines on unevenly spaced knots and repeated boundary;

Left plot: uniform cubic B-splines with equidistant knots

Right plot: non-uniform cubic B-splines with unevenly spaced knots and duplicated boundary knots

B-spline basis

- B-splines can be computed as differences of truncated power functions
- The general formula for equally-spaced knots is

$$B_j(x) = \frac{(-1)^{M+1} \Delta^{M+1} f_j(x, M)}{h^M M!}$$

satisfying

$$\sum_{i} B_{j}(x) = 1$$

where $f_j(x, M) = (x - \xi_j)_+^M$, h is is the distance between knots and Δ^O is the Oth order difference with

$$\Delta f_j(x, M) = f_j(x, M) - f_{j-1}(x, M),$$

$$\Delta^2 f_j(x, M) = \Delta(\Delta f_j(x, M)) = f_j(x, M) - 2f_{j-1}(x, M) + f_{j-2}(x, M)$$

P-splines

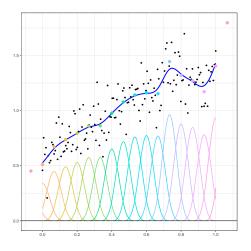

- There is an intermediate solution between regression and smoothing splines, proposed more recently by Eilers and Marx (1996)
- P-splines use a basis of (quadratic or cubic) B-splines, B,
 computed on x and using equally-spaced knots. Minimize

$$\|y - B\beta\|^2 + \lambda \|D\beta\|^2$$

where $D=\Delta^O$ is the matrix of Oth order differences, with $\Delta\beta_j=\beta_j-\beta_{j-1},\,\Delta^2\beta_j=\Delta(\Delta\beta_j)=\beta_j-2\beta_{j-1}+\beta_{j-2}$ and so on for higher O. Mostly O=2 or O=3 is used.

- Minimization leads to the system of equations

$$(B^t B + \lambda D^t D)\hat{\beta} = B^t y$$

The core idea of *P*-splines: a sum of B-spline basis functions, with gradually changing heights. The blue curve shows the *P*-spline fit, and the large dots the *B*-spline coefficients. R code in f-ps-show.R

Cross-validation

- We have that
$$\hat{y} = B(B^tB + \lambda D^tD)^{-1}B^ty = Sy$$

LOO = $\frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{y}_i^{(-i)})^2 = \frac{1}{n} \sum_{i=1}^{n} \left(\frac{y_i - \hat{y}_i}{1 - S_{ii}} \right)^2$

GCV =
$$\frac{1}{n} \sum_{i=1}^{n} \frac{(y_i - \hat{y}_i)^2}{(1 - \text{tr}(S)/n)^2}$$

 We can compute the trace of *S* without actually computing its diagonal, using

$$tr(S) = tr((B^tB + P)^{-1}B^tB) = tr(I_n - (B^tB + P)^{-1}P)$$
where $P = \lambda D^tD$

mcycle
